# Day-20 of #30daysofpython

## **Topic: Practise Exercises**

- Variable Assignment
- · List, tuples
- Sets
- · strings
- Dictionaries
- · If else elif
- Conditional loops
- · Functions & Methods

# Variable Assignment

### Rules for variable names

- · names can not start with a number
- names can not contain spaces, use \_ intead
- · names can not contain any of these symbols:

```
:'",<>/?|\!@#%^&*~-+
```

- it's considered best practice (<u>PEP8 (https://www.python.org/dev/peps/pep-0008/#function-and-variable-names</u>)) that names are lowercase with underscores
- avoid using Python built-in keywords like list and str
- avoid using the single characters 1 (lowercase letter el), 0 (uppercase letter oh) and I (uppercase letter eye) as they can be confused with 1 and 0

## **Dynamic Typing**

Python uses *dynamic typing*, meaning you can reassign variables to different data types. This makes Python very flexible in assigning data types; it differs from other languages that are *statically typed*.

```
In [1]:
```

```
my_dogs = 2
```

In [2]:

```
type(my_dogs)
```

Out[2]:

int

```
In [3]:
my_dogs
Out[3]:
2
In [4]:
my_dogs = ['Sammy', 'Frankie']
In [5]:
type(my_dogs)
Out[5]:
list
In [6]:
my_dogs
Out[6]:
['Sammy', 'Frankie']
```

## **Pros and Cons of Dynamic Typing**

#### **Pros of Dynamic Typing**

- · very easy to work with
- · faster development time

#### **Cons of Dynamic Typing**

- · may result in unexpected bugs!
- you need to be aware of type()

# **Assigning Variables**

Variable assignment follows name = object , where a single equals sign = is an assignment operator

```
In [5]:
a = 5
```

```
20/08/2021, 11:40
                                                   Variable Assignment - Jupyter Notebook
  In [6]:
  Out[6]:
  5
  Here we assigned the integer object 5 to the variable name a.
  Let's assign a to something else:
  In [7]:
  a = 10
  In [8]:
  а
  Out[8]:
  10
  You can now use a in place of the number 10:
  In [9]:
  a + a
```

# **Reassigning Variables**

Out[9]:

20

Python lets you reassign variables with a reference to the same object.

```
In [10]:
a = a + 10
In [11]:
а
Out[11]:
20
```

There's actually a shortcut for this. Python lets you add, subtract, multiply and divide numbers with reassignment using +=, -=, \*=, and /=.

```
In [12]:
a += 10

In [13]:
a
Out[13]:
30
In [14]:
a *= 2
In [15]:
a
Out[15]:
```

# Determining variable type with type()

You can check what type of object is assigned to a variable using Python's built-in type() function. Common data types include:

- int (for integer)
- float
- str (for string)
- list
- tuple
- dict (for dictionary)
- set
- bool (for Boolean True/False)

```
In [16]:
type(a)
Out[16]:
int
In [17]:
a = (1,2)
```

```
In [18]:
type(a)
Out[18]:
tuple
```

# **Simple Exercise**

This shows how variables make calculations more readable and easier to follow.

```
In [19]:
```

```
my_income = 100
tax_rate = 0.1
my_taxes = my_income * tax_rate
```

```
In [20]:
```

```
my_taxes
```

#### Out[20]:

10.0
